
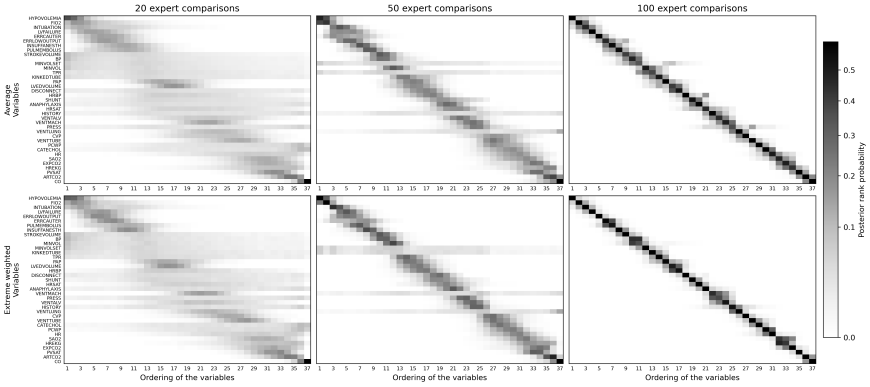
(a) Uncertainty of the variable ordering under different numbers of expert comparisons. The top row shows results for the Alarm network, and the bottom row shows results for the Random-100 network. From left to right, the panels correspond to 20, 50, and 100 expert comparisons, respectively. Darker shades indicate higher posterior rank probability. The rows correspond to variables, and the x-axis indicates the ordering positions of the variables.



(b) Uncertainty of the variable ordering in the Alarm network under mixed-quality experts. The top row shows simple averaging across five experts, whereas the bottom row uses inverse-variance-style weighting that emphasizes good experts and downweights poor experts. Columns correspond to expert-comparison budgets of 20, 50, and 100.

Figure 1: Posterior uncertainty in variable ordering under different expert-comparison settings and aggregation strategies.
